Abstract. Biological dinitrogen (N<sub>2</sub>) fixation provides the major source of new nitrogen (N) to the open ocean, contributing more than atmospheric deposition and riverine inputs to the N supply. Yet the fate of the diazotroph-derived N (DDN) in the planktonic food web is poorly understood. The main goals of this study were (i) to quantify how much of DDN is released to the dissolved pool during N<sub>2</sub> fixation and how much is transferred to bacteria, phytoplankton and zooplankton, and (ii) to compare the DDN release and transfer efficiencies under contrasting N<sub>2</sub> fixation activity and diversity in the oligotrophic waters of the western tropical South Pacific (WTSP) Ocean. We used nanometre-scale secondary ion mass spectrometry (nanoSIMS) coupled with <sup>15</sup>N<sub>2</sub> isotopic labelling and flow cytometry cell sorting to track the DDN transfer to plankton, in regions where the diazotroph community was dominated by either *Trichodesmium* or by UCYN-B. After 48 h, 20–40% of the N<sub>2</sub> fixed during the experiment was released to the dissolved pool when *Trichodesmium* dominated, while the DDN release was not quantifiable when UCYN-B dominated; 7–15% of the total fixed N (net N<sub>2</sub> fixation+release) was transferred to non-diazotrophic plankton within 48 h, with higher transfer efficiencies (15±3%) when UCYN-B dominated as compared to when *Trichodesmium* dominated (9±3%). The picocyanobacteria *Synechococcus* and *Prochlorococcus* were the primary beneficiaries of the DDN transferred (65–70%), followed by heterotrophic bacteria (23–34%). The DDN transfer in bacteria was higher (34±7%) in the UCYN-B-dominating experiment compared to the *Trichodesmium*-dominating experiments (24±5%). Regarding higher trophic levels, the DDN transfer to the dominant zooplankton species was less efficient when the diazotroph community was dominated by *Trichodesmium* (5–9% of the DDN transfer) than when it was dominated by UCYN-B (28±13% of the DDN transfer). To our knowledge, this study provides the first quantification of DDN release and transfer to phytoplankton, bacteria and zooplankton communities in open ocean waters. It reveals that despite UCYN-B fix N<sub>2</sub> at lower rates compared to *Trichodesmium* in the WTSP, the DDN from UCYN-B is much more available and efficiently transferred to the planktonic food web than the DDN originating from *Trichodesmium*.
